

# Public Review Draft

Proposed Addendum ak to Standard 189.1-2017

# Standard for the Design of High-Performance Green Buildings Except Low-Rise Residential Buildings

First Public Review Draft (August 2019)  
(Draft Shows Proposed Changes to Current Standard)

This draft has been recommended for public review by the responsible project committee. To submit a comment on this proposed standard, go to the ASHRAE website at [www.ashrae.org/standards-research--technology/public-review-drafts](http://www.ashrae.org/standards-research--technology/public-review-drafts) and access the online comment database. The draft is subject to modification until it is approved for publication by the Board of Directors and ANSI. Until this time, the current edition of the standard (as modified by any published addenda on the ASHRAE website) remains in effect. The current edition of any standard may be purchased from the ASHRAE Online Store at [www.ashrae.org/bookstore](http://www.ashrae.org/bookstore) or by calling 404-636-8400 or 1-800-727-4723 (for orders in the U.S. or Canada).

This standard is under continuous maintenance. To propose a change to the current standard, use the change submittal form available on the ASHRAE website, [www.ashrae.org](http://www.ashrae.org).

The appearance of any technical data or editorial material in this public review document does not constitute endorsement, warranty, or guaranty by ASHRAE of any product, service, process, procedure, or design, and ASHRAE expressly disclaims such.

**(This foreword is not part of this standard. It is merely informative and does not contain requirements necessary for conformance to the standard. It has not been processed according to the ANSI requirements for a standard and may contain material that has not been subject to public review or a consensus process. Unresolved objectors on informative material are not offered the right to appeal at ASHRAE or ANSI.)**

## Foreword

This addendum adds an informative appendix that documents how the source energy conversion factors and the CO<sub>2e</sub> emission factors in Table 7.5.2 were developed. This information is intended to provide guidance on how the values may be modified for other countries to suit the mix of generator types used to make electricity.

*[Note to Reviewers: This addendum makes proposed changes to the current standard. These changes are indicated in the text by underlining (for additions) and ~~strikethrough~~ (for deletions) except where the reviewer instructions specifically describe some other means of showing the changes. Only these changes to the current standard are open for review and comment at this time. Additional material is provided for context only and is not open for comment except as it relates to the proposed changes.]*

## Addendum ak to 189.1-2017

---

### *Add informative notes to Sections 7.5.2 and 7.5.3*

**7.5.2 Annual Carbon Dioxide Equivalent (CO<sub>2e</sub>).** The proposed design shall have an annual CO<sub>2e</sub> equal to or less than the annual CO<sub>2e</sub> of the baseline building design multiplied by the performance cost index target determined from 7.5.1. To determine the annual CO<sub>2e</sub> for each energy source in the baseline building design and proposed design, the energy consumption shall be multiplied by the CO<sub>2e</sub> emission factors from Table 7.5.2.

Informative Note: The values in Table 7.5.2 are derived from United States data. The procedures in Informative Appendix K may be used to develop CO<sub>2e</sub> emission factors when conditions are different.

**7.5.3 Zero Energy Performance Index.** The proposed building zero energy performance index (zEPI<sub>2004</sub>) with consideration of renewables shall be less than the target (zEPI<sub>2004 Target</sub>). zEPI<sub>2004</sub> and zEPI<sub>2004 Target</sub> shall be calculated as described below.

...

Informative Note: The values in Table 7.5.3 are derived from United States data. The procedures in Informative Appendix K may be used to develop source energy conversion factors when conditions are different.

*Add new Informative Appendix K. Note: this informative appendix is entirely new. For ease of reading, material is not shown underlined*

## INFORMATIVE APPENDIX K

### DERIVATION OF SOURCE ENERGY CONVERSION FACTORS AND CO<sub>2e</sub> EMISSION FACTORS

This informative appendix documents the procedures used to develop the source energy conversion factors and

CO<sub>2</sub>e emission factors in Table 7.5.2 and provides guidance on how the data can be modified for non-United States locations. Example data used to illustrate the procedure is for the entire United States electric grid in 2017. A similar procedure was used to develop source energy conversion factors and CO<sub>2</sub>e emission factors for the eGRID subregions, the only difference being the mix of electric generators and net generation.

**K1. SOURCE ENERGY CONVERSION FACTORS**

**K1.1 Source-Site Conversion Factors for Fossil Fuels**

For the United States, the source energy factors for fossil fuel delivered to buildings are listed in Table K1. These factors represent the energy required to extract, process, and deliver the fuel to the building per unit of energy in the fuel assuming the heating values listed in the table. These same values are used for fuels delivered to power plants.

**Table K1 – Source Energy Conversion Factors for Fuel Delivered to Buildings**

*Source: Michael Deru and Paul Torcellini, Source Energy and Emission Factors for Energy Use in Buildings, National Renewable Energy Laboratory, Technical Report NREL/TP-550-38617, Revised June 2007, Table 5.*

<i>Fuel</i>	<i>Source Energy Conversion Factor</i>	<i>Higher Heating Value</i>	
Anthracite Coal	1.029	12,700 Btu/lb	29,539 kJ/kg
Bituminous Coal	1.048	12,155 Btu/lb	28,270 kJ/kg
Sub-bituminous Coal	1.066	8,818 Btu/lb	20,509 kJ/kg
Lignite Coal	1.102	6,465 Btu/lb	15,038 kJ/kg
Natural Gas	1.092	1,010 Btu/ft <sup>3</sup> *	37,631 kJ/m <sup>3</sup> *
Residual Fuel Oil	1.191	149,500 Btu/gal	41,666 kJ/L
Distillate Fuel Oil	1.158	138,700 Btu/gal	38,656 kJ/L
Gasoline	1.187	100,000 Btu/gal	27,870 kJ/L
LPG	1.151	91,000 Btu/gal	25,362 kJ/L
Kerosene	1.205	135,000 Btu/gal	27,870 kJ/L

This data was derived from the life cycle inventory data from the U.S. LCI Database, maintained by NREL.

\* Heating value for 60°F and 14.70 psia (15.6°C and 101325 Pa).

**K1.2 Source Conversion Factors for Electricity**

For electricity, the source energy conversion factors represent the energy required to extract, process, and deliver fuel to the power plants plus the energy used at the power plant to generate electricity. This source energy is then divided by the net electricity generation, in similar units. The net electricity generation is the power from domestic production that reaches customers and excludes transmission and distribution losses.

*K1.2.1 Heat Rates*

The source energy input into making electricity is calculated by multiplying the net electric generation for each generation source by the heat rate for that generation source. Table K2 has the heat rates used to generate the

Permission to republish or redistribute must be obtained from the MOS.*

source energy inputs for the United States. The source-site multipliers from Table K1 are also applied to these values to account for the upstream energy used in extraction, processing and delivery.

**Table K2 – Heat Rates for Electric Generation – 2017**

Source: Energy Information Administration, *Monthly Energy Review*, Table A6, except for biomass and non-combustible renewables

<i>Fuel Used for Electricity Generation</i>	<i>Heat Rate</i>	
	<i>(Btu/kWh)</i>	<i>(kWh/kWh)</i>
Coal	10,493	3.08
Petroleum	10,811	3.17
Natural Gas	7,870	2.31
Total Fossil Fuels	9,232	2.71
Nuclear	10,459	3.07
Biomass <sup>1</sup>	15,968	4.68
Non-Combustible Renewables	0	0

<sup>1</sup> The heat rate for biomass is the 2017 consumption from Table 10.2c of the EIA Monthly Energy Report divided by the 2017 biomass net generation from Table 7.2b of the MER.

*K1.2.2 Electric Generation Mix*

Table K3 shows the amount of electricity generated in the United States for 2017, broken down by the generator type. Data in this table will generally be the most significant change for non-United States locations. The last column shows the source energy used for each generator. The source energy is calculated by multiplying the electric generation times the heat rate from Table K2 and the source energy conversion factor from Table K1.

**Table K3 – United States Electricity Generation Mix for 2017**

Source: Energy Information Agency, *Monthly Energy Report*, Table 7.2b

<i>Generator Type</i>	<i>Domestic Electric Generation (billions kWh)</i>	<i>Source Energy (quads)</i>
Coal	1,199	13.19
Petroleum	20	0.25
Natural Gas	1,180	10.14
Nuclear	805	8.42
Hydroelectric	298	0
Biomass	32	0.52
Geothermal	16	0
Solar	52	0
Wind	254	0
Total	3,858	32.53

*K1.2.3 Net Generation*

© 2019 ASHRAE

*This draft is covered under ASHRAE copyright. The appearance of any technical data or editorial material in this publication document does not constitute endorsement, warranty, or guaranty by ASHRAE of any product, service, process, procedure, design or the like and ASHRAE expressly disclaims such. Permission to republish or redistribute must be obtained from the MOS.*

The net electricity delivered to customers accounts for energy losses due to pumped or battery storage as well as transmission and distribution losses. Table K4 shows the net electricity generation in the United States for 2017. For 2017, transmission and distribution losses were about 6.1%.

**Table K4 – United States Net Generation for 2017**

Source: Energy Information Agency, *Monthly Energy Report*, Table 7.1

	<i>Net Electricity (billions kWh)</i>
Domestic Generation (from Table K3)	3,858
Pumped Storage	-6
T&D Losses	-245
Delivered to Customers from Domestic Generation	3,606
Delivered to Customers from Domestic Generation (quads)	12.30

**K1.2.4 Source Energy Conversion Factor for Electricity**

The source energy conversion factor is calculated as shown below in Equation K1. For the United States national grid in 2017, the numerator is 32.53 quads from the last column of Table K3 and the denominator is last row from Table K4. The result is 32.53 quads divided by 12.30 quads for a source energy conversion factor of 2.64. A similar process is used for each of the eGRID regions.

Equation K1

$$r_e = \frac{\sum_{f=1}^n EG_f \times HR_f \times r_f}{NG}$$

where

- $r_e$  = Source energy conversion factor for electricity, unitless.
- $EG_f$  = Electric generation at the power plant for the  $f^{th}$  energy form, billions kWh (from Table K3).
- $HR_f$  = Heat rate for the  $f^{th}$  energy form, kWh/kWh (from Table K2).
- $r_f$  = Source energy conversion factor for the  $f^{th}$  energy form, unitless (from Table K1). A source energy conversion factor of 1.025 is used for biomass to account for the energy required for harvesting and transportation.
- $NG$  = Net generation, e.g. power from domestic production that is delivered to customers, billions kWh (from Table K4).
- $f$  = Index for the energy form.
- $n$  = Number of energy forms used to make electricity.

**K2. CARBON DIOXIDE EQUIVALENT (CO<sub>2</sub>E) EMISSIONS**

**K2.1. Fossil Fuel Emissions**

Fossil fuel combustion results in the release of three significant greenhouse gases: carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O). These gases are released at the point of combustion but emissions also result from

Permission to republish or redistribute must be obtained from the MOS.*

the mining of coal, production of oil and gas, refinement, pumping, trucking, rail transport and/or piping of fuels. These direct and indirect emission rates are used for both direct combustion in commercial boilers as well as in power plants, except as noted in Table K5. These values are not expected to change significantly for other locations or jurisdictions.

Small amounts of CH<sub>4</sub> and N<sub>2</sub>O are released (mostly upstream), but these gases have a much larger impact on global warming than CO<sub>2</sub> for a given mass of emissions. The global warming potential for 20-year cumulative forcing as determined by the International Panel of Climate Change (IPCC) is used in the analysis (see Emissions from non-combustible renewable energy generators, e.g. wind, solar and hydro, are assumed to be zero. Emissions at geothermal plants are small, but not zero. A value of 20 lb of CO<sub>2</sub> per MWh of production is assumed based on geothermal plants in the western United States. Table K6 and these 20-year weights are used to determine the CO<sub>2e</sub> values in Table K5. The total emissions from Table K5 are used for fuels delivered directly to buildings or power plants.

**Table K5 – Direct and Indirect Emissions from Fossil Fuels Use**

*Source: Michael Deru and Paul Torcellini, Source Energy and Emission Factors for Energy Use in Buildings, National Renewable Energy Laboratory, Technical Report NREL/TP-550-38617, Revised June 2007, except as noted below.. These NREL data in this report were derived from the United States Life Cycle Inventory (LCI) Database, maintained by NREL.*

<i>Fuel</i>	<i>Carbon Dioxide (CO<sub>2</sub>)</i>	<i>Methane (CH<sub>4</sub>)</i>	<i>Nitrous Oxide (N<sub>2</sub>O)</i>	<i>CO<sub>2e</sub></i>

Residual Fuel Oil	663.46	0.8748	0.0042	738
Distillate Fuel Oil	641.56	0.8642	0.0044	715
Coal <sup>2</sup>	764.42	1.1972	0.1038	892
Gasoline	656.41	1.0225	0.0047	744
Biomass <sup>3</sup>	371.64	0.0442	0.0414	386

1. Indirect methane emissions for natural gas are based on total losses of 1.4% for gas delivered to power plants and 1.8% for gas delivered to buildings, per Table ES-1 of *Life Cycle Analysis of Natural Gas Extraction and Power Generation*, August 30, 2016, DOE/NETL-2015/1714.
2. The NREL report gives values for various types of coal, but bituminous is used for this analysis since it is most common form in the USA.
3. Values for biomass were not reported in the NREL document. Figures in this table were derived separately from EIA data and information from the California Air Resources Board (CARB). The cumulative net emissions for the 20-year period are calculated by subtracting the estimated counterfactual emissions.

Emissions from non-combustible renewable energy generators, e.g. wind, solar and hydro, are assumed to be zero. Emissions at geothermal plants are small, but not zero. A value of 20 lb of CO<sub>2</sub> per MWh of production is assumed based on geothermal plants in the western United States.

**Table K6 – Global Warming Potential (unitless multipliers)**

Source: [https://en.wikipedia.org/wiki/Global\\_warming\\_potential](https://en.wikipedia.org/wiki/Global_warming_potential)

	Carbon Dioxide (CO <sub>2</sub> )	Methane (CH <sub>4</sub> )	Nitrous Oxide (N <sub>2</sub> O)
20 Year Cumulative Forcing	1	84	264
100 Year Cumulative Forcing	1	28	265

Source: IPCC 2013, AR4 without climate carbon feedbacks

**K2.2. Emissions from Electricity Generation**

Emissions related to electricity generation are calculated by multiplying the total emissions from Table K5 for each CO<sub>2</sub>e emitting fuel times the quantity of that fuel from Table K3 that is used to generate electricity. The sum is then divided by the net electricity generation from Table K4, as shown in Equation K2.

Equation K2

$$CO_2e = \frac{\sum_{f=1}^n F_f \times E_f \times C}{NG}$$

Where

CO<sub>2</sub>e = Carbon dioxide equivalent emissions, lb/MWh

F<sub>f</sub> = The quantity of carbon emitting fuel used at the power plant for the f<sup>th</sup> energy form, quads (from Table K3)

The appearance of any technical data or editorial material in this publication document does not constitute endorsement, warranty, or guaranty by ASHRAE of any product, service, process, procedure, design or the like and ASHRAE expressly disclaims such. Permission to republish or redistribute must be obtained from the MOS.*

- $E_f$  = The total emissions rate for the  $f^{th}$  energy form, kWh/kWh (from Table K5)
- $C$  = Conversion factor to change quads to MWh
- $NG$  = Net generation, e.g. power from domestic production delivered to the customers, billions kWh (from Table K4)
- $f$  = Index for the energy form
- $n$  = Number of energy forms used to make electricity

**K2.3. District Energy Systems**

District energy systems are assumed to use electricity for cooling and natural gas for heating. Values in Table 7.5.2 were calculated based on the district energy efficiency assumptions shown in Table K7. These or other assumptions appropriate for local conditions should be used when values in Table 7.5.2 are modified. Please note that the published values for district energy systems can be overridden through district energy modeling procedures recognized in Appendix C.

**Table K7 – Efficiency Assumptions for District Energy Systems**

Heating Efficiency	70%	Overall Efficiency
Cooling Efficiency	4.4	Overall COP
Losses CHW	5%	
Losses HW	10%	
Losses Steam	15%	

Source: Defaults from 2.4.1.2.3 of LEED District Energy Guide
